Whenever you use any of these options like **Auto-Correct Load, API Bulk Load, Triggers, pre-load/post-load commands** on target table, its always recommended to describe the steps in an annotation note. It helps in many situations, for example, you renamed the target table name in underlying database and you might want to change it in your dataflow as well. Once, you replace the existing table with the renamed table, you might forgot to set some of your target table options. It really helps a lot particularly in such kind of instances, you can pretty much refer your annotation note and set all your target table options with ease.

Hope this tip helps!
